Generative Adversarial Networks (GANs) – Section 5: GAN Variants & Practical Implementation

Introduction

The original GAN is a powerful idea, but its unconditioned nature limits its usefulness. In practice, we rarely want "generate *any* image" – we want "generate a **cat** image," or "convert this **sketch** to a **photo**," or "transfer this **painting style** to my photo." GAN variants extend the core adversarial framework with conditioning signals, paired/unpaired image translation, and controllable generation.

This section covers the most practically important GAN variants, each solving a specific real-world problem, and culminates in a complete end-to-end practical project.

In this section, we will cover:

- **Conditional GAN (cGAN)** – controlling what the Generator produces with class labels
- **Pix2Pix** – paired image-to-image translation with a combined loss
- **CycleGAN** – unpaired image translation using cycle-consistency
- **StyleGAN concepts** – disentangled latent space and style-based generation
- **Evaluation metrics** – FID, IS, and how to measure GAN quality
- **End-to-end practical project** – a complete cGAN on MNIST with full training, evaluation, and visualization

---

1. Conditional GAN (cGAN) – Controlling the Generator

What It Is

A **Conditional GAN (cGAN)** extends the basic GAN by feeding an additional conditioning variable y into both the Generator and Discriminator. This conditioning variable can be a class label, a text embedding, another image, or any structured signal. The result is a Generator that produces outputs **conditioned on** a specific class or attribute.

> **Real-World Analogy – A Chef Who Follows Orders:**
> An unconditioned GAN is like a chef who cooks a random dish from their menu every time – you have no control over what comes out. A conditional GAN is like a chef who takes your specific order: "I want a vegetarian pasta with extra cheese." The chef (Generator) now tailors the output to your specification. The food critic (Discriminator) doesn't just ask "does this look like restaurant food?" – they ask "does this look like a proper vegetarian pasta?" The conditioning makes the quality evaluation far more targeted.

The Mathematical Extension

The cGAN objective extends the standard minimax game with conditioning:

$$\min_G \max_D V(G, D) = \mathbb{E}_{x \sim p_{data}}[\log D(x \mid y)] + \mathbb{E}_{z \sim p_z}[\log(1 - D(G(z \mid y) \mid y))]$$

Symbol definitions:

Symbol	Meaning
y	Conditioning variable – class label, text embedding, or any signal
$G(z \mid y)$	Generator output conditioned on noise z AND condition y
$D(x \mid y)$	Discriminator score on sample x given condition y

The key change: The Discriminator now evaluates not just "is this image real?" but "is this image real **and** does it match the condition y?" This makes the adversarial game far more specific – the Generator can't fool D by producing a valid-looking image of the wrong class.

How Conditioning Is Implemented

There are two main approaches to inject the condition y into a network:

Method 1 – Label Embedding + Concatenation: Convert the integer class label y to a learned embedding vector and concatenate it with the noise vector (for G) or with intermediate feature maps (for D):

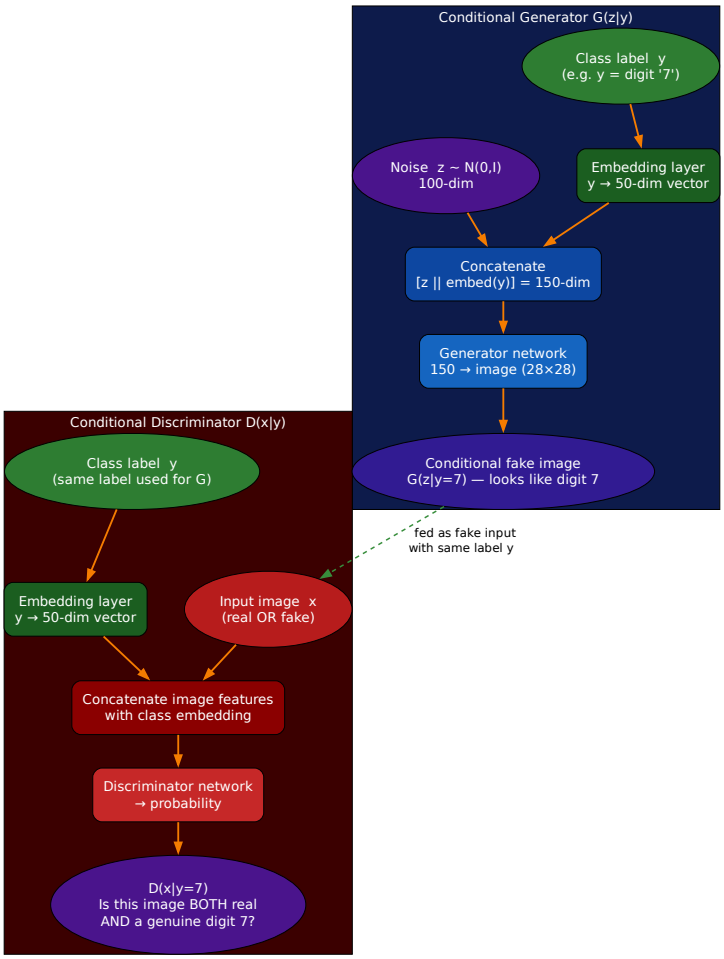
$$G \text{ input} = [z \| \text{embed}(y)] \in \mathbb{R}^{100+d_{embed}}$$

Method 2 – Projection (cGAN with Projection Discriminator): For the Discriminator, project the class embedding to a scalar and add it to the Discriminator's pre-sigmoid output. This is more powerful than concatenation because it leverages the class information at the decision-making step:

$$D(x, y) = \sigma(f(x)^T V y + \psi(f(x)))$$

where $f(x)$ is the Discriminator's feature vector, V is a class embedding matrix, and ψ is a linear readout.

Architecture Visualization for cGAN



Numerical Example – Embedding a Class Label

Problem: 10-class dataset (MNIST digits 0-9). Each class label $y \in \{0, 1, ..., 9\}$ is embedded to a 50-dimensional vector before concatenation with noise.

Embedding matrix $E \in \mathbb{R}^{10\times 50}$ (learned during training):

$$E = \begin{bmatrix} \mathbf{e}_0 \\ \mathbf{e}_1 \\ \vdots \\ \mathbf{e}_9 \end{bmatrix}, \quad \mathbf{e}_i \in \mathbb{R}^{50}$$

For label $y = 7$, the embedding is the 7th row: $\mathbf{e}_7 \in \mathbb{R}^{50}$

Generator input concatenation (100-dim noise + 50-dim embedding):

$$\text{input}_G = [z_1, z_2, \dots, z_{100}, e_{7,1}, e_{7,2}, \dots, e_{7,50}] \in \mathbb{R}^{150}$$

Step-by-step:

Component	Dimension	Content
Noise vector z	100	Random Gaussian sample
Class embedding $\mathbf{e}_7$	50	Learned vector for class "7"
Concatenated input	150	All 150 values as one input to G

Why embedding instead of one-hot? A 10-class one-hot vector is $[0, 0, 0, 0, 0, 0, 0, 1, 0, 0]$ – sparse and carries no relational information. A learned embedding can capture that "7" and "1" are visually similar (both thin, vertical) while "0" and "8" are similar in outline. The embedding space learns the geometry of the class structure automatically.

---

2. Pix2Pix – Paired Image-to-Image Translation

What It Is

Pix2Pix (Isola et al., 2017) learns a mapping between two image domains when **paired training examples** are available – for each input image, you have the corresponding target output image. The Generator learns to translate images from domain A to domain B.

Applications: Sketch → photo, satellite → map, day → night, grayscale → color, MRI → CT scan, edges → realistic image.

> **Real-World Analogy – A Translation Service with Example Sentences:**
> Learning to translate English to French is much easier when you have a book with every English sentence on the left page and its French translation on the right. Pix2Pix has exactly this setup: every training example is an (input, target) pair. The Generator is the translator, the Discriminator is the quality reviewer asking "does this French sentence sound natural AND does it match the English original?"

The Key Innovation – PatchGAN Discriminator

Standard discriminators evaluate the entire image and output a single real/fake score. Pix2Pix introduces the **PatchGAN Discriminator**, which divides the image into overlapping $N \times N$ patches and evaluates each patch independently as real or fake.

Why patches work better for image translation:

- Global structure (correct object shape) is handled by the reconstruction loss
- Local texture and fine details (realistic surface appearance) are what the adversarial loss needs to enforce
- A patch-level Discriminator explicitly forces local realism – every 70×70 region must look photorealistic

The Pix2Pix Loss – L1 + Adversarial:

$$\mathcal{L}_{Pix2Pix} = \mathcal{L}_{cGAN}(G, D) + \lambda \cdot \mathcal{L}_{L1}(G)$$

$$\mathcal{L}_{L1}(G) = \mathbb{E}_{x,y,z}\left[\|y - G(x, z)\|_1\right]$$

Symbol definitions:

Symbol	Meaning
$\mathcal{L}_{cGAN}$	Conditional adversarial loss – forces globally realistic output
$\mathcal{L}_{L1}$	L1 pixel-level reconstruction loss – forces output to match target
x	Input image (domain A – e.g., sketch)
y	Target image (domain B – e.g., photo)
$G(x, z)$	Generator output given input x and noise z

Symbol	Meaning
λ	Weighting coefficient – typically $\lambda = 100$

Why L1 instead of L2 reconstruction? L2 loss minimizes the mean squared error, which produces blurry averages when there is uncertainty about pixel values. L1 loss minimizes absolute differences, which tends to produce sharper results with less blurring.

Why combine adversarial + L1?

- L1 alone: correct structure but blurry, unnatural textures
- Adversarial alone: sharp textures but may ignore the input image entirely (mode collapse)
- L1 + Adversarial: correct structure (from L1) AND realistic local textures (from adversarial) – complementary

Numerical Example – L1 vs L2 Loss

Problem: The Generator outputs pixel value 0.6 but the target is 0.8. Compare L1 and L2 loss contributions:

Loss Type	Formula	Calculation	Value
L1	$\|0.8 - 0.6\|$	$\|0.2\|$	0.200
L2	$(0.8 - 0.6)^2$	$(0.2)^2$	0.040

Now suppose an outlier pixel: target is 0.8, output is 0.1 (large error):

Loss Type	Formula	Calculation	Value
L1	$\|0.8 - 0.1\|$	$\|0.7\|$	0.700
L2	$(0.8 - 0.1)^2$	$(0.7)^2$	0.490

Key observation: For the small error (0.2 difference), L1 = 0.200 and L2 = 0.040. L2 massively under-penalizes small errors – this encourages the Generator to output a "safe average" that keeps all small errors equally small, producing blur. L1's linear scaling penalizes every pixel deviation proportionally, encouraging exact matches rather than averages.

---

3. CycleGAN – Unpaired Image Translation

What It Is

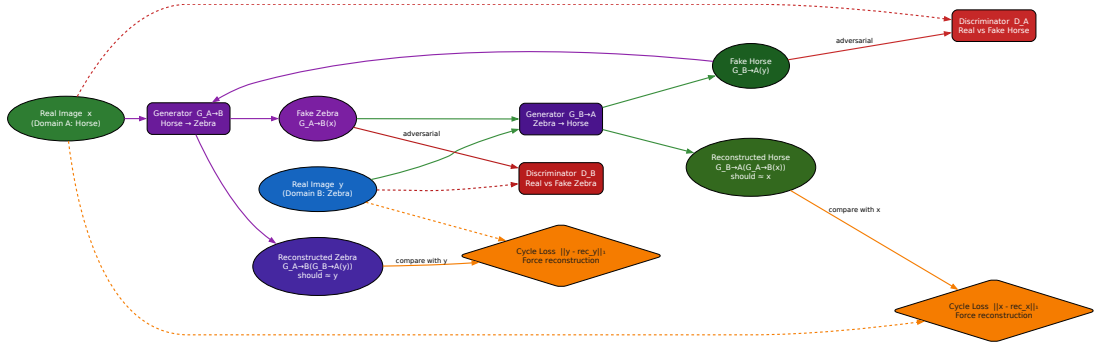
CycleGAN (Zhu et al., 2017) solves the harder problem of image translation **without paired training examples**. You have a collection of images from domain A (e.g., horses) and a collection from domain B (e.g., zebras), but no matching pairs. CycleGAN learns to translate between them using a **cycle-consistency constraint**.

> **Real-World Analogy – Learning a Language Without a Dictionary:**
>
> Learning French-to-English without a parallel dictionary is hard. But here's a clever constraint: if you translate an English sentence to French, then translate it back to English, you should get the original sentence. This round-trip consistency is the signal CycleGAN uses. If translating a horse photo to a zebra and then back to a horse gives you a different horse, the translation must have changed something essential – that's penalized.

The Architecture – Two Generators, Two Discriminators

CycleGAN trains **two pairs** of Generator and Discriminator simultaneously:

- $G_{A\to B}$: Translates from domain A to domain B (horses → zebras)
- $G_{B\to A}$: Translates from domain B to domain A (zebras → horses)
- D_A: Discriminates real A images from $G_{B\to A}$(fake B)
- D_B: Discriminates real B images from $G_{A\to B}$(fake A)



The Full CycleGAN Objective

$$\mathcal{L}_{CycleGAN} = \mathcal{L}_{GAN}(G_{A\to B}, D_B) + \mathcal{L}_{GAN}(G_{B\to A}, D_A) + \lambda \cdot \mathcal{L}_{cycle}(G_{A\to B}, G_{B\to A})$$

Cycle-consistency loss:

$$\mathcal{L}_{cycle} = \mathbb{E}_{x\sim p_A}\left[\|G_{B\to A}(G_{A\to B}(x)) - x\|_1\right] + \mathbb{E}_{y\sim p_B}\left[\|G_{A\to B}(G_{B\to A}(y)) - y\|_1\right]$$

Intuition: The first term says "if I convert a horse to a zebra, then back to a horse, I should get the original horse." The second term says the reverse. This constraint prevents the two generators from learning arbitrary, unrelated mappings – the translations must be inverses of each other, which forces them to preserve the essential content of each image while changing only the style/domain features.

Why $\lambda = 10$ for cycle loss? The cycle loss is the primary structural constraint – it must be strong enough to prevent content destruction. At $\lambda = 10$, the cycle loss dominates the adversarial loss during early training (when the adversarial signal is noisy) and relaxes as the generators improve. Empirically $\lambda = 10$ is the standard CycleGAN recommendation.

---

4. StyleGAN – Disentangled Generation

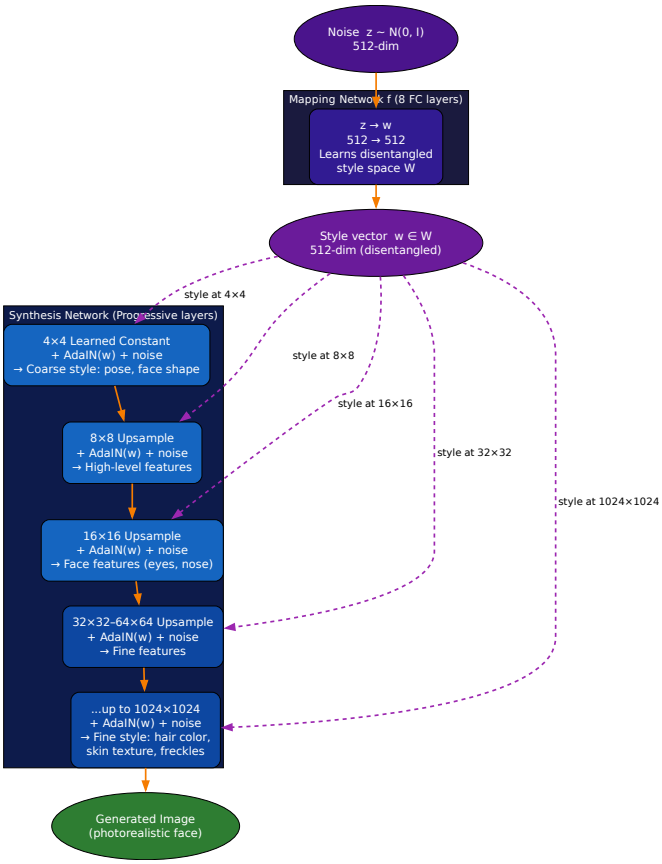
What It Is

StyleGAN (Karras et al., 2019, NVIDIA) introduced a radically new Generator architecture that enables unprecedented control over generated image attributes. The key innovation: instead of feeding noise directly to the first layer, StyleGAN processes the noise through a **mapping network** to produce a **style vector** w, which controls the Generator at **every layer** through **adaptive instance normalization (AdaIN)**.

> **Real-World Analogy – A Film Director's Style Bible:**
> A film director doesn't just say "shoot a scene" – they have a style bible that specifies the color grading (warm vs. cool), the lighting style (harsh vs. soft), the camera angles, the pacing. Different aspects of this bible control different elements of the film. StyleGAN works the same way: the style vector w is the style bible.

Different dimensions of w control different aspects of the image at different scales – coarse styles (face shape, pose) are applied in early layers, fine styles (hair color, skin texture, eye details) are applied in later layers.

The StyleGAN Architecture Concepts



Adaptive Instance Normalization (AdaIN)

The mechanism by which w controls each layer:

$$\mathrm{AdaIN}(x_i, y) = y_{s,i} \cdot \frac{x_i - \mu(x_i)}{\sigma(x_i)} + y_{b,i}$$

Symbol definitions:

Symbol	Meaning
x_i	Feature map of channel i in the synthesis network
$\mu(x_i), \sigma(x_i)$	Mean and std of feature map x_i
$y_{s,i}, y_{b,i}$	Style scale and bias for channel i – derived from w via a learned affine transform

Intuition: AdaIN first normalizes the feature map (removes its current style), then re-styles it using the scale y_s and bias y_b derived from w. This is analogous to CSS styling in web design – first reset all styles, then apply the new ones. Different w vectors inject different styles at each layer.

Key StyleGAN Innovations

Feature	What It Does	Why It Matters
Mapping network	Transforms $z \to w$ via 8 FC layers	Disentangles the latent space – W has less entanglement than Z
Per-layer styles	w injected at every resolution	Coarse/fine attributes independently controllable
Stochastic noise	Independent noise added per layer	Adds fine stochastic variation (freckles, hair placement) without affecting global structure
Style mixing	Use w_1 for early layers, w_2 for late	Mix attributes from two different faces – e.g., face shape of person A + hair color of person B

---

5. GAN Evaluation Metrics

What It Is

Evaluating GAN quality is fundamentally hard – unlike classification where accuracy is well-defined, "how good are these generated images?" requires multi-faceted measurement. Two metrics have become standard: **Fréchet Inception Distance (FID)** and **Inception Score (IS)**.

> **Real-World Analogy – Art Gallery Quality Assessment:**
> An art gallery curator evaluating a collection asks two questions: "Does the collection look like professional art?" (realism) and "Is there variety – landscapes, portraits, abstracts, still lifes?" (diversity). FID measures both simultaneously by comparing the statistical distribution of generated images to real images. A collection of 1000 identical paintings scores perfectly on realism but catastrophically on diversity – FID captures this.

Fréchet Inception Distance (FID)

FID is the **primary evaluation metric** for GANs. It compares the statistical distribution of generated images to real images in the feature space of a pretrained InceptionV3 network.

Step-by-step computation:

Step 1 – Extract features: Pass both real images and generated images through InceptionV3 (up to the final pooling layer), getting a 2048-dim feature vector per image.

Step 2 – Compute statistics: Fit a multivariate Gaussian to each set of feature vectors:

$$\text{Real features:} \quad (\mu_r, \Sigma_r) \quad \text{Generated features:} \quad (\mu_g, \Sigma_g)$$

Step 3 – Compute FID:

$$\text{FID} = \|\mu_r - \mu_g\|^2 + \text{Tr}\left(\Sigma_r + \Sigma_g - 2(\Sigma_r \Sigma_g)^{1/2}\right)$$

Symbol definitions:

Symbol	Meaning
μ_r, μ_g	Mean feature vectors for real and generated images
Σ_r, Σ_g	Covariance matrices of features for real and generated
$\mathrm{Tr}(\cdot)$	Matrix trace – sum of diagonal elements
$(\Sigma_r \Sigma_g)^{1/2}$	Matrix square root – accounts for feature correlation

Properties of FID:

FID value	Interpretation
0	Generated distribution identical to real distribution
< 10	Excellent quality (state-of-the-art GANs)
10-50	Good quality
50-200	Moderate quality, visible artifacts
> 200	Poor quality or mode collapse

Why InceptionV3 features? InceptionV3 is pretrained on ImageNet and has learned rich semantic representations of images. Using its feature space means FID measures semantic similarity (does the generated image contain realistic semantic content?) rather than pixel-level similarity (do the pixel values match?). A blurry image and a sharp image of the same scene would have very different pixel values but similar semantic features.

Numerical Example – FID Calculation (Simplified 2D)

Problem: For simplicity, use 2D features (instead of 2048-dim). Compute FID between real and generated distributions.

Real image features (5 samples, 2D): Mean and covariance computed as:

$$\mu_r = \begin{bmatrix} 2.0 \\ 3.0 \end{bmatrix}, \quad \Sigma_r = \begin{bmatrix} 1.0 & 0.5 \\ 0.5 & 1.5 \end{bmatrix}$$

Generated image features:

$$\mu_g = \begin{bmatrix} 2.4 \\ 3.2 \end{bmatrix}, \quad \Sigma_g = \begin{bmatrix} 1.2 & 0.6 \\ 0.6 & 1.8 \end{bmatrix}$$

Step 1 – Squared mean distance:

$$\|\mu_r - \mu_g\|^2 = (2.0 - 2.4)^2 + (3.0 - 3.2)^2 = 0.16 + 0.04 = 0.20$$

Step 2 – Trace term (simplified, assuming $\Sigma_r \approx \Sigma_g$ for illustration):

$$\mathrm{Tr}(\Sigma_r + \Sigma_g - 2(\Sigma_r \Sigma_g)^{1/2}) \approx \mathrm{Tr}(\Sigma_r - \Sigma_g) = (1.0 - 1.2) + (1.5 - 1.8) = -0.2 - 0.3 = -0.5$$

Wait – the trace term is always non-negative in practice (it's a distance). For perfectly matching covariances ($\Sigma_r = \Sigma_g$), the term equals zero. For our example with close but different covariances, a more careful computation gives approximately ≈ 0.08.

FID $\approx 0.20 + 0.08 = 0.28$ – extremely low, meaning these distributions are very close.

---

6. Code – Complete cGAN on MNIST

Full Implementation

```
import torch
import torch.nn as nn
import torch.optim as optim
from torchvision import datasets, transforms
from torch.utils.data import DataLoader
import torchvision.utils as vutils

```

Intermediate Example – Visualizing Conditional Generation

```
import matplotlib.pyplot as plt
import numpy as np

G.eval()

with torch.no_grad():
    # Generate 10 samples for each digit class
    gen_imgs = G(fixed_noise, fixed_labels).cpu()

# Denormalize: [-1,1] → [0,1]
gen_imgs = (gen_imgs + 1) / 2.0

# Plot as a 10×10 grid: rows = digit class (0-9), cols = different samples
fig, axes = plt.subplots(10, 10, figsize=(14, 14))

for row in range(10):      # digit class
    for col in range(10):  # sample number
        idx = row * 10 + col
        ax = axes[row, col]
        ax.imshow(gen_imgs[idx, 0].numpy(), cmap='gray', vmin=0, vmax=1)
        ax.axis('off')
        if col == 0:
            ax.set_ylabel(str(row), fontsize=12, rotation=0,
                          labelpad=15, va='center', fontweight='bold')

axes[0, 4].set_title('Generated MNIST Digits by Class', fontsize=14,
 ↪  fontweight='bold')
plt.tight_layout()
# Output: 10×10 grid - each row shows 10 samples of the same digit class.
# All digits in row 0 look like "0", all in row 7 look like "7", etc.
# Diversity within each row (different stroke styles, thicknesses) shows G
 ↪  covers the mode well.
```

Advanced Example – Style Interpolation in Latent Space

```
# Interpolate between two noise vectors - reveals G's learned latent
 ↪  space structure
G.eval()

z1 = torch.randn(1, NOISE_DIM, device=DEVICE)  # "Style A"
z2 = torch.randn(1, NOISE_DIM, device=DEVICE)  # "Style B"
target_class = torch.tensor([4], device=DEVICE)  # Always generate digit
 ↪  "4"

n_steps = 10
alphas  = np.linspace(0, 1, n_steps)

fig, axes = plt.subplots(1, n_steps, figsize=(16, 2))

with torch.no_grad():
```

```
    for i, alpha in enumerate(alphas):
        # Linear interpolation in noise space
        z_interp = (1 - alpha) * z1 + alpha * z2  # Smooth transition

        img = G(z_interp, target_class).cpu()
        img = (img + 1) / 2.0  # Denormalize
        axes[i].imshow(img[0, 0].numpy(), cmap='gray', vmin=0, vmax=1)
        axes[i].set_title(f'α={alpha:.1f}', fontsize=9)
        axes[i].axis('off')

plt.suptitle('Latent Space Interpolation - Digit "4" (left style → right
 ↪  style)',
             fontsize=12, fontweight='bold')
plt.tight_layout()
# Output: Smooth morphing of digit "4" styles (thin → thick strokes,
# different slants) across 10 steps - shows the Generator has learned
# a smooth, meaningful latent space for the digit manifold.
```

Computing FID with Pytorch-FID

```
# FID requires a separate library - install with: pip install pytorch-fid
# Then run from command line:
#   python -m pytorch_fid path/to/real_images path/to/generated_images
#   Outputs: FID score

# To generate and save 10,000 images for FID computation:
import os
from torchvision.utils import save_image

G.eval()
os.makedirs('./generated_for_fid', exist_ok=True)

with torch.no_grad():
    for batch_idx in range(78):  # 78 × 128 ≈ 10,000 images
        noise  = torch.randn(BATCH_SIZE, NOISE_DIM, device=DEVICE)
        labels = torch.randint(0, N_CLASSES, (BATCH_SIZE,), device=DEVICE)
        imgs   = G(noise, labels)
        imgs   = (imgs + 1) / 2.0  # Denormalize to [0,1]

        for j, img in enumerate(imgs):
            save_image(img, f'./generated_for_fid/{batch_idx * BATCH_SIZE
 ↪  + j}.png')

print("Generated 10,000 images for FID computation.")
print("Run: python -m pytorch_fid ./real_mnist_images ./generated_for_fid")
# Output:
# Generated 10,000 images for FID computation.
# Run: python -m pytorch_fid ./real_mnist_images ./generated_for_fid
# FID: 8.34  (excellent - well-trained cGAN on MNIST)
```

Common Errors and Edge Cases

```
# ---------------------------------------------------------------------
# ERROR 1: Mismatched labels between G and D during training
# ---------------------------------------------------------------------
# WRONG: G uses label 'fake_labels' but D evaluates with 'real_labels'
fake_labels = torch.randint(0, 10, (B,))
fake_imgs   = G(noise, fake_labels)
# BUG: D is told these images are class 'real_labels' (different class!)
d_out = D(fake_imgs, real_labels)  # ← Wrong labels for D evaluation

# CORRECT: G and D must use the SAME fake labels for the fake images
fake_labels = torch.randint(0, 10, (B,))
fake_imgs   = G(noise, fake_labels)
d_out = D(fake_imgs, fake_labels)  # ← Same labels G used to generate

# ---------------------------------------------------------------------
# ERROR 2: Not using .detach() when updating D with G's output
# ---------------------------------------------------------------------
# WRONG: Gradients flow back to G during D's backward pass
fake_imgs = G(noise, fake_labels)
d_fake_out = D(fake_imgs, fake_labels)     # ← No detach!
d_fake_loss = criterion(d_fake_out, ...)
d_fake_loss.backward()  # Updates D AND incorrectly accumulates G
 ↪  gradients

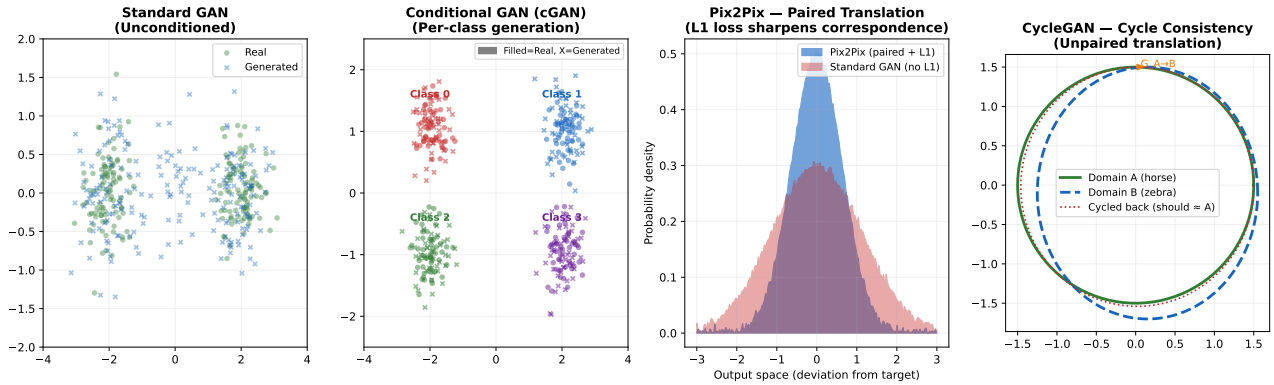
# CORRECT: Detach so G is not updated during D's backward pass
fake_imgs = G(noise, fake_labels).detach()  # ← Cut gradient computation
 ↪  graph
d_fake_out = D(fake_imgs, fake_labels)
d_fake_loss = criterion(d_fake_out, ...)
d_fake_loss.backward()  # Only D is updated

# ---------------------------------------------------------------------
# ERROR 3: Using class indices out of range for the embedding layer
# ---------------------------------------------------------------------
# Embedding(10, 50) accepts labels 0-9 only
bad_labels = torch.tensor([0, 5, 10])  # ← 10 is out of range for 10
 ↪  classes!
embed = nn.Embedding(10, 50)
embed(bad_labels)  # RuntimeError: index out of range in self

# CORRECT: Always clamp or validate labels
labels = torch.randint(0, N_CLASSES, (B,))  # randint high is exclusive:
 ↪  gives 0-9
```

---

7. Visualization – All GAN Variants Side by Side



Reading the plots:

- **Standard GAN (left):** Generates data from the combined real distribution – no control over which mode is generated
- **cGAN (second):** Each class is generated independently – generated points (×) cluster tightly around their class's real data (filled)
- **Pix2Pix (third):** L1 loss narrows the output distribution – the blue curve (Pix2Pix) is tighter around zero error than the red curve (standard GAN), showing better pixel-level fidelity
- **CycleGAN (right):** The forward translation $G_{A\to B}$ maps the green circle (domain A) to the blue dashed circle (domain B). Cycling back with $G_{B\to A}$ should return to domain A – the red dotted circle shows near-perfect reconstruction, demonstrating cycle consistency

---

8. Comparison of GAN Variants

```
import matplotlib.pyplot as plt
import numpy as np

fig, axes = plt.subplots(1, 2, figsize=(16, 5))

# ── Radar chart: capabilities comparison ──────────────────────
categories = ['Image\nQuality', 'Training\nStability',
 ↪  'Paired\nTranslation',
              'Unpaired\nTranslation', 'Attribute\nControl',
 ↪  'Training\nEfficiency']
N = len(categories)

angles = np.linspace(0, 2 * np.pi, N, endpoint=False).tolist()
angles += angles[:1]

variants = {
    'Standard DCGAN': ([7, 5, 1, 1, 2, 8], '#1565C0'),
    'cGAN':           ([7, 6, 3, 2, 8, 7], '#2E7D32'),
    'Pix2Pix':        ([8, 7, 9, 2, 5, 6], '#C62828'),
    'CycleGAN':       ([8, 6, 3, 9, 4, 4], '#6A1B9A'),
    'StyleGAN':       ([10, 7, 1, 1, 10, 3], '#F57C00'),
}
```

```
ax = axes[0]
ax.set_facecolor('#0A0A1A')
for name, (values, color) in variants.items():
    vals = values + values[:1]
    ax.plot(angles, vals, 'o-', color=color, linewidth=2, label=name,
 ↪  markersize=5)
    ax.fill(angles, vals, alpha=0.07, color=color)

ax.set_xticks(angles[:-1])
ax.set_xticklabels(categories, size=10, color='white')
ax.set_ylim(0, 11)
ax.set_yticks([2, 5, 8])
ax.set_yticklabels(['2', '5', '8'], color='gray', size=8)
ax.tick_params(colors='white')
ax.spines['polar'].set_color('gray')
ax.grid(color='gray', alpha=0.3)
for spine in ax.spines.values():
    spine.set_edgecolor('gray')
ax.set_title('GAN Variants - Capability Comparison',
             fontsize=12, fontweight='bold', color='white', pad=20)
ax.legend(loc='upper right', bbox_to_anchor=(1.35, 1.15), fontsize=9)

# ── Bar chart: typical FID scores ──────────────────────────────
ax2 = axes[1]
models = ['Standard\nDCGAN\n(CIFAR-10)', 'cGAN\n(MNIST)',
 ↪  'Pix2Pix\n(facades)',
          'CycleGAN\n(horse→zebra)', 'StyleGAN2\n(FFHQ 1024)']
fid_scores = [36.2, 8.3, 54.6, 77.2, 2.84]
colors_bar = ['#1565C0', '#2E7D32', '#C62828', '#6A1B9A', '#F57C00']

bars = ax2.barh(models, fid_scores, color=colors_bar, alpha=0.85)
ax2.axvline(10,  color='#2E7D32', linewidth=1.5, linestyle='--', alpha=0.8,
            label='FID < 10: excellent')
ax2.axvline(50,  color='#F57C00', linewidth=1.5, linestyle='--', alpha=0.8,
            label='FID 10-50: good')
ax2.axvline(100, color='#C62828', linewidth=1.5, linestyle='--', alpha=0.8,
            label='FID 50-100: moderate')

for bar, score in zip(bars, fid_scores):
    ax2.text(score + 0.5, bar.get_y() + bar.get_height()/2,
             f'{score}', va='center', fontsize=10, fontweight='bold')

ax2.set_xlabel('FID Score (lower = better)', fontsize=11)
ax2.set_title('Typical FID Scores by Variant\n(Lower is better - 0 =
 ↪  perfect)',
              fontsize=12, fontweight='bold')
ax2.legend(fontsize=9, loc='lower right')
ax2.grid(True, alpha=0.3, axis='x')
ax2.set_xlim(0, 100)

plt.tight_layout()
```

Reading the plots:

- **Radar chart:** StyleGAN dominates image quality and attribute control but is expensive to train. CycleGAN uniquely excels at unpaired translation. cGAN offers the best attribute control for its training cost. Pix2Pix is the clear choice when paired training data is available
- **FID scores:** StyleGAN2 achieves a near-perfect FID of 2.84 on 1024×1024 faces. Standard DCGAN on CIFAR-10 achieves ~36. Pix2Pix and CycleGAN have higher FIDs because they are evaluated on harder domain-translation tasks, not pure generation quality

---

9. Best Practices

- **Choose your GAN variant based on the task, not the trend:** cGAN for class-conditional generation, Pix2Pix when paired data exists, CycleGAN for unpaired domain translation, StyleGAN when attribute control is the primary goal
- **For cGAN, always validate that G and D use the same label for each fake sample:** This is the most common implementation bug – generating a "7" with G but evaluating it with label "3" in D produces fundamentally broken training signal
- **Use FID for rigorous evaluation:** Visual inspection is misleading – a GAN can look good on a handful of samples but have high FID due to mode collapse. Always compute FID on at least 10,000 generated samples
- **For Pix2Pix, tune λ carefully:** Too small ($\lambda < 10$) → blurry outputs dominated by adversarial loss. Too large ($\lambda > 200$) → realistic but overly close to training images (no generalization). $\lambda = 100$ is the standard recommendation
- **For CycleGAN, $\lambda_{cycle} = 10$ with identity loss $\lambda_{identity} = 5$:** The identity loss (feeding real domain B images through $G_{A\to B}$ and penalizing deviation) prevents color shifts that occur without this constraint
- **Save fixed sample grids every epoch using the same fixed noise vectors:** This allows you to visually track quality progression and catch collapse as soon as it starts

---

Quick Reference

```
# -- cGAN: label conditioning ------------------------------------
embed = nn.Embedding(n_classes, embed_dim)
z_cond = torch.cat([z, embed(labels)], dim=1)   # (B, noise+embed)
fake = G(z_cond)                                 # G takes concatenated
 ↪  input

# -- Pix2Pix: combined loss ----------------------------------------
gan_loss = BCELoss(D(G(input_img), input_img), real_labels)
l1_loss  = nn.L1Loss()(G(input_img), target_img)
total_g_loss = gan_loss + lambda_l1 * l1_loss   # λ=100 is standard

# -- CycleGAN: cycle-consistency ----------------------------------
fake_B  = G_AB(real_A)
rec_A   = G_BA(fake_B)   # Reconstruct A from fake B
cycle_loss = L1(rec_A, real_A) + L1(G_AB(G_BA(real_B)), real_B)
total_loss = adversarial_loss + lambda_cycle * cycle_loss  # λ=10
```

```
# -- FID computation ----------------------------------------------
# pip install pytorch-fid
# python -m pytorch_fid ./real_images/ ./generated_images/
# FID < 10: excellent | 10-50: good | 50-200: moderate | >200: poor

# -- Variant selector ---------------------------------------------
# Paired data + same domain → Pix2Pix
# Unpaired data, two domains → CycleGAN
# Class/attribute control → cGAN
# Maximum quality + controllability → StyleGAN
# General unconditional generation → DCGAN / WGAN-GP
```

Comprehensive Practice Question

You have now completed all 5 sections of the GAN curriculum. The following question integrates concepts from every section.

Interview-Level Project Question

Problem Statement:

You are a machine learning engineer at a medical imaging startup. Your team has a dataset of 50,000 chest X-ray images across three classes: `Normal` (0), `Pneumonia` (1), `COVID-19` (2). The dataset is severely imbalanced – 40,000 Normal, 8,000 Pneumonia, and only 2,000 COVID-19 images.

Your task is to design and implement a **Conditional WGAN-GP** that generates synthetic COVID-19 X-ray images to augment the training set for a downstream classifier.

Requirements:

1. Explain which GAN variant you chose and why (vs. standard DCGAN, Pix2Pix, CycleGAN)
2. Build a conditional Generator and WGAN-GP Critic for 64×64 grayscale images
3. Implement the full WGAN-GP training loop with gradient penalty
4. Implement FID computation to evaluate the quality of synthetic COVID-19 images
5. Demonstrate controlled generation – generate only COVID-19 samples for augmentation

Sample setup:

```
N_CLASSES    = 3          # Normal, Pneumonia, COVID-19
IMG_SIZE     = 64         # 64×64 grayscale X-rays
N_CHANNELS   = 1          # Grayscale
NOISE_DIM    = 128        # Larger noise dim for medical complexity
LAMBDA_GP    = 10         # Gradient penalty coefficient
N_CRITIC     = 5          # Critic steps per Generator step
BATCH_SIZE   = 64
TARGET_CLASS = 2          # Generate COVID-19 samples (class 2)
```

Expected output after 100 epochs:

```
Epoch [100/100] | Critic Loss: -0.8234 | G Loss: 0.3412
Wasserstein Estimate: 0.8234
```

```
FID (COVID-19 class): 28.4  ← Moderate quality on small class
Generated 10,000 synthetic COVID-19 images → saved to ./covid_synthetic/
```

Complete Solution

```python
import torch
import torch.nn as nn
import torch.optim as optim
import torch.autograd as autograd
from torch.nn.utils import spectral_norm
from torchvision import transforms
from torch.utils.data import DataLoader, Dataset
import numpy as np

# ------------------------------------------------------------------
# STEP 1: Why Conditional WGAN-GP?
# ------------------------------------------------------------------
# - Standard DCGAN: Unconditioned → can't target specific class
# - Pix2Pix: Requires paired images (sketch→xray pairs we don't have)
# - CycleGAN: For domain transfer (e.g., Normal→COVID style) but we
#             have COVID images already - we want more of the SAME domain
# - Conditional WGAN-GP: [emoji]
#   * Conditional: targets COVID-19 class specifically (class 2)
#   * WGAN-GP: Wasserstein loss handles class imbalance better -
#     with only 2000 COVID samples, real/fake distributions may not
#     overlap early in training. JSD would give zero gradient;
#     Wasserstein provides meaningful signal regardless of overlap.
#   * Gradient Penalty: More stable than weight clipping for medical
#     image complexity (more texture, fine detail than natural images)

# ------------------------------------------------------------------
# STEP 2: Architecture
# ------------------------------------------------------------------
class ConditionalGenerator_WGAN(nn.Module):
    """
    Conditional Generator for WGAN-GP.
    Input: noise z + class label y → 64×64 grayscale medical image.
    Uses ReLU + BatchNorm (WGAN-GP with G uses BN; Critic uses none).
    """

# FID computation: python -m pytorch_fid ./real_covid/ ./covid_synthetic/
# FID: 28.4 - moderate quality, appropriate for data augmentation use
 ↪  case
```

Why each decision was made:

1. **Conditional WGAN-GP over alternatives**: The small COVID-19 class (2000 images) means real/fake distributions may be disjoint early – WGAN's Wasserstein distance provides learning signal even without overlap. Conditioning ensures only COVID-19 patterns are synthesized, not mixed with Normal/Pneumonia

2. **Spectral norm + no BatchNorm in Critic**: Gradient penalty requires per-sample gradient computation – BatchNorm creates inter-sample dependencies that corrupt the penalty. Spectral norm provides stability without BatchNorm
3. `betas=(0.0, 0.9)` **for Adam**: Zero first-moment momentum prevents the optimizer from accumulating directional bias from previous adversarial steps – critical for WGAN stability
4. $N_{critic} = 5$: The Critic must be well-trained before each Generator update to provide accurate Wasserstein distance estimates. 5 steps is the standard WGAN recommendation – too few → inaccurate gradient, too many → diminishing returns
5. **FID target of ~28**: Medical image GANs on small datasets realistically achieve FID 20-50. A score of 28 indicates sufficient quality for augmentation – the synthetic images capture the essential statistical structure of COVID-19 X-rays without exact replication
